Support Vector Machines

These slides are based on Arthur Gretton's UCL course on Advanced Topics in Machine Learning

Optimization and the Lagrangian

Optimization problem on $x \in \mathbb{R}^d$ / primal,

 $\begin{array}{ll} \text{minimize} & f_0(x) \\ \text{subject to} & f_i(x) \leq 0 \\ & h_j(x) = 0 \end{array} \qquad \qquad i = 1, \dots, m \\ j = 1, \dots r. \end{array}$

• domain $\mathcal{D} := \bigcap_{i=0}^{m} \operatorname{dom} f_i \cap \bigcap_{j=1}^{r} \operatorname{dom} h_j$ (nonempty).

• p*: the (primal) optimal value

Idealy we would want an unconstrained problem

minimize
$$f_0(x) + \sum_{i=1}^m I_-(f_i(x)) + \sum_{j=1}^r I_0(h_j(x))$$
,
here $I_-(u) = \begin{cases} 0, & u \le 0\\ \infty, & u > 0 \end{cases}$ and $I_0(u) = \begin{cases} 0, & u = 0\\ \infty, & u \ne 0 \end{cases}$.

wł

The Lagrangian $L : \mathbb{R}^d \times \mathbb{R}^m \times \mathbb{R}^r \to \mathbb{R}$ is an (easier to optimize) lower bound on the original problem:

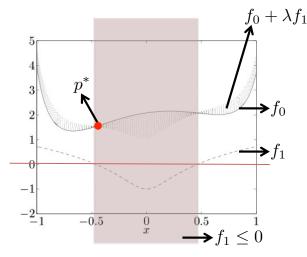

$$L(x, \lambda, \nu) := f_0(x) + \sum_{i=1}^m \underbrace{\lambda_i f_i(x)}_{\leq I_-(f_i(x))} + \sum_{j=1}^r \underbrace{\nu_j h_j(x)}_{\leq I_0(h_j(x))},$$

The vectors λ and ν are called Lagrange multipliers or dual variables. To ensure a lower bound, we require $\lambda \succeq 0$ $I_{-}(\cdot)$

 $f_i(x)$

 $h_i(x)$

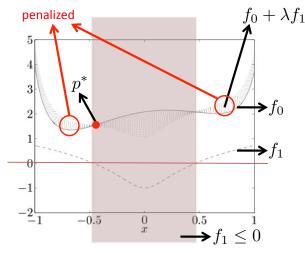

Simplest example: minimize over *x* the function $L(x, \lambda) = f_0(x) + \lambda f_1(x)$

Reminders:

- *f*₀ is function to be minimized.
- $f_1 \leq 0$ is inequality constraint
- $\lambda \ge 0$ is Lagrange multiplier
- p* is minimum f₀ in constraint set

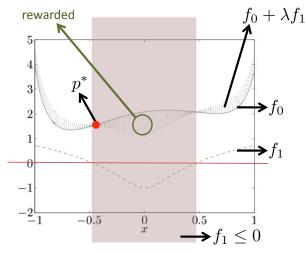

Simplest example: minimize over *x* the function $L(x, \lambda) = f_0(x) + \lambda f_1(x)$

Reminders:

- *f*₀ is function to be minimized.
- $f_1 \leq 0$ is inequality constraint
- $\lambda \ge 0$ is Lagrange multiplier
- p* is minimum f₀ in constraint set

Simplest example: minimize over *x* the function $L(x, \lambda) = f_0(x) + \lambda f_1(x)$

Reminders:

- *f*₀ is function to be minimized.
- $f_1 \leq 0$ is inequality constraint
- $\lambda \ge 0$ is Lagrange multiplier
- p* is minimum f₀ in constraint set

Lagrange dual: lower bound on optimum p^*

The Lagrange dual function: minimize Lagrangian When $\lambda \succeq 0$ and $f_i(x) \le 0$, Lagrange dual function is

$$g(\lambda, \nu) := \min_{x \in \mathcal{D}} L(x, \lambda, \nu).$$

A **dual feasible** pair (λ, ν) is a pair for which $\lambda \succeq 0$ and $(\lambda, \nu) \in \text{dom}(g)$. We will show: for any $\lambda \succeq 0$ and ν ,

 $g(\lambda,\nu) \leq f_0(x)$

wherever

$$\begin{array}{ll} f_i(x) & \leq 0 \\ h_j(x) & = 0 \end{array}$$

(including at optimal point $f_0(x^*) = p^*$).

Lagrange dual is a lower bound on p^*

Assume \tilde{x} is feasible, i.e. $f_i(\tilde{x}) \leq 0$, $h_i(\tilde{x}) = 0$, $\tilde{x} \in \mathcal{D}$, $\lambda \succeq 0$. Then

$$\sum_{i=1}^m \lambda_i f_i(\tilde{x}) + \sum_{i=1}^r \nu_i h_i(\tilde{x}) \le 0$$

Thus

$$g(\lambda,\nu) := \min_{x \in \mathcal{D}} \left(f_0(x) + \sum_{i=1}^m \lambda_i f_i(x) + \sum_{i=1}^r \nu_i h_i(x) \right)$$

$$\leq f_0(\tilde{x}) + \sum_{i=1}^m \lambda_i f_i(\tilde{x}) + \sum_{i=1}^r \nu_i h_i(\tilde{x})$$

$$\leq f_0(\tilde{x}).$$

This holds for every feasible \tilde{x} , hence lower bound holds.

Best lower bound: maximize the dual

Best lower bound $g(\lambda, \nu)$ on the optimal solution p^* of original problem: Lagrange dual problem

maximize	$g(\lambda, u)$
subject to	$\lambda \succeq 0.$

Dual feasible: (λ, ν) with $\lambda \succeq 0$ and $g(\lambda, \nu) > -\infty$.

Dual optimal: solutions (λ^*, ν^*) to the dual problem, d^* is optimal value. Weak duality always holds:

Strong duality: (does not always hold, conditions given later):

$$d^* = p^*.$$

If strong duality holds: can solve the **dual problem** to find p^* .

How do we know if strong duality holds?

Conditions under which strong duality holds are called **constraint qualifications** (they are sufficient, but not necessary) (Probably) best known sufficient condition: Strong duality holds if

• Primal problem is convex, i.e. of the form

minimize $f_0(x)$ subject to $f_i(x) \le 0$ i = 1, ..., nAx = b

for convex f_0, \ldots, f_m , and

 Slater's condition: there exists a strictly feasible point *x*, such that *f_i*(*x*) < 0, *i* = 1,...,*n* (reduces to the existence of any feasible point when inequality constraints are affine, i.e., *Cx* ≤ *d*).

A consequence of strong duality...

Assume primal is equal to the dual. What are the consequences?

- x^* solution of original problem (minimum of f_0 under constraints),
- (λ^*, ν^*) solutions to dual

$$f_0(x^*) = g(\lambda^*, \nu^*)$$

$$= \min_{\substack{(\text{g definition}) \\ (\text{inf definition}) \\ (4)}} \int_{\substack{x \in \mathcal{D} \\ x \in \mathcal{D}}} \left(f_0(x) + \sum_{i=1}^m \lambda_i^* f_i(x) + \sum_{i=1}^p \nu_i^* h_i(x) \right)$$

$$= \int_{\substack{(\text{inf definition}) \\ (4)}} f_0(x^*) + \sum_{i=1}^m \lambda_i^* f_i(x^*) + \sum_{i=1}^p \nu_i^* h_i(x^*)$$

(4): (x^*, λ^*, ν^*) satisfies $\lambda^* \succeq 0$, $f_i(x^*) \le 0$, and $h_i(x^*) = 0$.

... is complementary slackness

From previous slide,

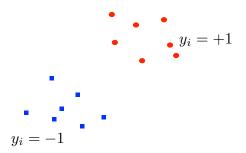

$$\sum_{i=1}^{m} \lambda_i^* f_i(x^*) = 0,$$
(1)

which is the condition of complementary slackness. This means

$$egin{array}{lll} \lambda_i^* > 0 & \Longrightarrow & f_i(x^*) = 0, \ f_i(x^*) < 0 & \Longrightarrow & \lambda_i^* = 0. \end{array}$$

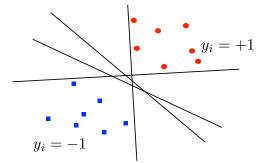

From λ_i , read off which inequality constraints are strict.

Classify two clouds of points, where there exists a hyperplane which linearly separates one cloud from the other without error.

Data given by $\{x_i, y_i\}_{i=1}^n, x_i \in \mathbb{R}^p, y_i \in \{-1, +1\}$

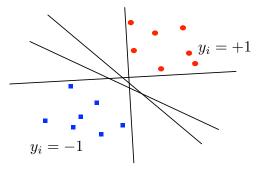

Classify two clouds of points, where there exists a hyperplane which linearly separates one cloud from the other without error.

Hyperplane equation $w^{\top}x + b = 0$. Linear discriminant given by

 $\hat{y}(x) = \operatorname{sign}(w^{\top}x + b)$

Classify two clouds of points, where there exists a hyperplane which linearly separates one cloud from the other without error.

For a datapoint close to the decision boundary, a small change leads to a change in classification. Can we make the classifier more robust?

Classify two clouds of points, where there exists a hyperplane which linearly separates one cloud from the other without error.

Smallest distance from each class to the separating hyperplane $w^{\top}x + b$ is called the **margin**.

Department of Statistics, Oxford

Maximum margin classifier, linearly separable case

This problem can be expressed as follows:

$$\max_{w,b} (\text{margin}) = \max_{w,b} \left(\frac{1}{\|w\|} \right)$$

subject to

$$\begin{cases} w^{\top} x_i + b \ge 1 & i : y_i = +1, \\ w^{\top} x_i + b \le -1 & i : y_i = -1. \end{cases}$$

The resulting classifier is

 $\hat{y}(x) = \operatorname{sign}(w^{\top}x + b),$

We can rewrite to obtain a quadratic program:

$$\min_{w,b} \frac{1}{2} \|w\|^2$$

subject to

$$y_i(w^{\top}x_i+b) \ge 1.$$

Maximum margin classifier: with errors allowed

Allow "errors": points within the margin, or even on the wrong side of the decision boundary. Ideally:

$$\min_{w,b} \left(\frac{1}{2} \|w\|^2 + C \sum_{i=1}^n \mathbb{I}[y_i (w^\top x_i + b) < 0] \right),$$

where *C* controls the tradeoff between maximum margin and loss. Replace with **convex upper bound**:

$$\min_{w,b} \left(\frac{1}{2} \|w\|^2 + C \sum_{i=1}^n h\left(y_i \left(w^\top x_i + b \right) \right) \right)$$

with hinge loss,

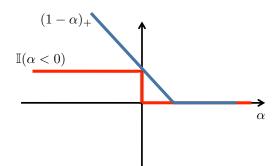

$$h(\alpha) = (1 - \alpha)_{+} = \begin{cases} 1 - \alpha, & 1 - \alpha > 0\\ 0, & \text{otherwise.} \end{cases}$$

Maximizing the Margin

Hinge loss

Hinge loss:

$$h(\alpha) = (1 - \alpha)_{+} = \begin{cases} 1 - \alpha, & 1 - \alpha > 0\\ 0, & \text{otherwise.} \end{cases}$$

Support vector classification

Substituting in the hinge loss, we get a standard regularised empirical risk minimisation problem - where regularisation naturally arises from the margin penalty.

$$\min_{w,b} \left(\frac{1}{2} \|w\|^2 + C \sum_{i=1}^n h\left(y_i \left(w^\top x_i + b \right) \right) \right).$$

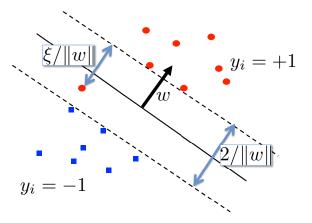

Using substitution $\xi_i = h(y_i(w^{\top}x_i + b))$, we obtain an equivalent formulation (standard C-SVM):

$$\min_{w,b,\xi} \left(\frac{1}{2} \|w\|^2 + C \sum_{i=1}^n \xi_i \right)$$

subject to

$$\xi_i \ge 0$$
 $y_i \left(w^\top x_i + b \right) \ge 1 - \xi_i$

Support vector classification

Duality

As a convex constrained optimization problem with affine constraints in w, b, ξ , strong duality holds.

minimize
$$f_0(w, b, \xi) := \frac{1}{2} ||w||^2 + C \sum_{i=1}^n \xi_i$$

subject to $f_i(w, b, \xi) := 1 - \xi_i - y_i (w^\top x_i + b) \le 0, \ i = 1, \dots, n$
 $f_{n+i}(w, b, \xi) := -\xi_i \le 0, \ i = 1, \dots, n.$

Support vector classification: Lagrangian

The Lagrangian: $L(w, b, \xi, \alpha, \lambda) =$

$$\frac{1}{2} \|w\|^2 + C \sum_{i=1}^n \xi_i + \sum_{i=1}^n \alpha_i \left(1 - \xi_i - y_i \left(w^\top x_i + b\right)\right) + \sum_{i=1}^n \lambda_i (-\xi_i)$$

with dual variable constraints

$$\alpha_i \ge 0, \qquad \lambda_i \ge 0.$$

Minimize wrt the primal variables w, b, and ξ . Derivative wrt w:

$$\frac{\partial L}{\partial w} = w - \sum_{i=1}^{n} \alpha_i y_i x_i = 0 \qquad w = \sum_{i=1}^{n} \alpha_i y_i x_i.$$

Derivative wrt b:

$$\frac{\partial L}{\partial b} = \sum_{i} y_i \alpha_i = 0.$$

Support vector classification: Lagrangian

Derivative wrt ξ_i :

$$\frac{\partial L}{\partial \xi_i} = C - \alpha_i - \lambda_i = 0 \qquad \alpha_i = C - \lambda_i.$$

Since $\lambda_i \geq 0$,

 $\alpha_i \leq C.$

Now use complementary slackness:

Non-margin SVs (margin errors): $\alpha_i = C > 0$:

• We immediately have $y_i(w^{\top}x_i + b) = 1 - \xi_i$.

Also, from condition $\alpha_i = C - \lambda_i$, we have $\lambda_i = 0$, so $\xi_i \ge 0$

Margin SVs: $0 < \alpha_i < C$:

• We again have $y_i (w^T x_i + b) = 1 - \xi_i$.

2 This time, from $\alpha_i = C - \lambda_i$, we have $\lambda_i > 0$, hence $\xi_i = 0$.

Non-SVs (on the correct side of the margin): $\alpha_i = 0$:

• From $\alpha_i = C - \lambda_i$, we have $\lambda_i > 0$, hence $\xi_i = 0$.

2 Thus,
$$y_i(w^{\top}x_i+b) \geq 1$$

The support vectors

We observe:

- The solution is sparse: points which are neither on the margin nor "margin errors" have $\alpha_i = 0$
- The support vectors: only those points on the decision boundary, or which are margin errors, contribute.
- Influence of the non-margin SVs is bounded, since their weight cannot exceed C.

Support vector classification: dual function

Thus, our goal is to maximize the dual,

$$g(\alpha, \lambda) = \frac{1}{2} \|w\|^2 + C \sum_{i=1}^n \xi_i + \sum_{i=1}^n \alpha_i \left(1 - y_i \left(w^\top x_i + b\right) - \xi_i\right) \\ + \sum_{i=1}^n \lambda_i (-\xi_i) \\ = \frac{1}{2} \sum_{i=1}^n \sum_{j=1}^n \alpha_i \alpha_j y_i y_j x_i^\top x_j + C \sum_{i=1}^n \xi_i - \sum_{i=1}^n \sum_{j=1}^n \alpha_i \alpha_j y_i y_j x_i^\top x_j \\ - b \sum_{i=1}^n \alpha_i y_i + \sum_{i=1}^n \alpha_i - \sum_{i=1}^n \alpha_i \xi_i - \sum_{i=1}^n (C - \alpha_i) \xi_i \\ = \sum_{i=1}^n \alpha_i - \frac{1}{2} \sum_{i=1}^n \sum_{j=1}^n \alpha_i \alpha_j y_i y_j x_i^\top x_j.$$

Dual C-SVM

maximize
$$\sum_{i=1}^{n} \alpha_i - \frac{1}{2} \sum_{i=1}^{n} \sum_{j=1}^{n} \alpha_i \alpha_j y_j y_j x_i^{\top} x_j$$
,

subject to the constraints

$$0 \le \alpha_i \le C, \quad \sum_{i=1}^n y_i \alpha_i = 0$$

This is a quadratic program. From α , obtain the hyperplane with

$$w = \sum_{i=1}^{n} \alpha_i y_i x_i$$

(follows from complementary slackness in the derivation of the dual). Offset *b* can be obtained from any of the margin SVs (for which $\alpha_i \in (0, C)$): $1 = y_i (w^T x_i + b)$.

Solution depends on data through inner products only

Dual program

$$\max_{\alpha} \sum_{i=1}^{n} \alpha_{i} - \frac{1}{2} \sum_{i,j=1}^{n} \alpha_{i} \alpha_{j} y_{i} y_{j} \mathbf{x}_{i}^{\mathsf{T}} \mathbf{x}_{j} \qquad \text{subject to} \quad \begin{cases} \sum_{i=1}^{n} \alpha_{i} y_{i} = 0\\ 0 \leq \alpha \leq C \end{cases}$$

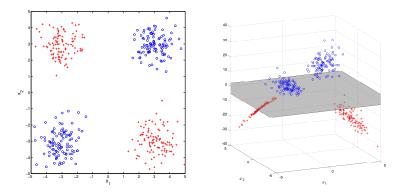

only depends on inputs x_i through their inner products (similarities) with other inputs. Decision function

$$\hat{y}(x) = \operatorname{sign}(w^{\top}x + b) = \operatorname{sign}(\sum_{i=1}^{n} \alpha_i y_i x_i^{\top} x + b)$$

also depends only on the similarity of a test point *x* to the training points x_i . Thus, we do not need explicit inputs - just their pairwise similarities. Key property: even if p > n, it is still the case that $w \in \text{span} \{x_i : i = 1, ..., n\}$ (normal vector of the hyperplane lives in the subspace spanned by the datapoints).

Department of Statistics, Oxford

Beyond Linear Classifiers

- No linear classifier separates red from blue.
- Linear separation after mapping to a higher dimensional feature space:

$$\mathbb{R}^2 \ni \left(\begin{array}{cc} x^{(1)} & x^{(2)} \end{array} \right)^\top = x \quad \mapsto \quad \varphi(x) = \left(\begin{array}{cc} x^{(1)} & x^{(2)} & x^{(1)}x^{(2)} \end{array} \right)^\top \in \mathbb{R}^3$$

Non-Linear SVM

- Consider the dual C-SVM with explicit non-linear transformation $x \mapsto \varphi(x)$:
- $\max_{\alpha} \sum_{i=1}^{n} \alpha_i \frac{1}{2} \sum_{i,j=1}^{n} \alpha_i \alpha_j y_i y_j \varphi(x_i)^\top \varphi(x_j) \quad \text{subject to} \quad \begin{cases} \sum_{i=1}^{n} \alpha_i y_i = 0\\ 0 \leq \alpha \leq C \end{cases}$ Suppose p = 2, and we would like to introduce quadratic non-linearities,

$$\varphi(x) = \left(1, \sqrt{2}x^{(1)}, \sqrt{2}x^{(2)}, \sqrt{2}x^{(1)}x^{(2)}, \left(x^{(1)}\right)^2, \left(x^{(2)}\right)^2\right)^\top$$

Then

$$\begin{aligned} \varphi(x_i)^{\top}\varphi(x_j) &= 1 + 2x_i^{(1)}x_j^{(1)} + 2x_i^{(2)}x_j^{(2)} + 2x_i^{(1)}x_i^{(2)}x_j^{(1)}x_j^{(2)} \\ &+ \left(x_i^{(1)}\right)^2 \left(x_j^{(1)}\right)^2 + \left(x_i^{(2)}\right)^2 \left(x_j^{(2)}\right)^2 = (1 + x_i^{\top}x_j)^2 \end{aligned}$$

- Since only inner products are needed, non-linear transform need not be computed explicitly - inner product between features can be a simple function (kernel) of x_i and x_i : $k(x_i, x_i) = \varphi(x_i)^\top \varphi(x_i) = (1 + x_i^\top x_i)^2$
- *d*-order interactions can be implemented by $k(x_i, x_i) = (1 + x_i^{\top} x_i)^d$ (polynomial kernel). Never need to compute explicit feature expansion of dimension $\binom{p+d}{d}$ where this inner product happens!

Department of Statistics. Oxford

SC4/SM8 ATSML, HT2019

Kernel SVM: Kernel trick

Kernel SVM with k(x_i, x_j). Non-linear transformation x → φ(x) still present, but implicit (coordinates of the vector φ(x) are never computed).

$$\max_{\alpha} \sum_{i=1}^{n} \alpha_{i} - \frac{1}{2} \sum_{i,j=1}^{n} \alpha_{i} \alpha_{j} y_{i} y_{j} k(x_{i}, x_{j}) \quad \text{subject to} \quad \begin{cases} \sum_{i=1}^{n} \alpha_{i} y_{i} = 0\\ 0 \leq \alpha \leq C \end{cases}$$

• Prediction? $\hat{y}(x) = \text{sign}(w^{\top}\varphi(x) + b)$, where $w = \sum_{i=1}^{n} \alpha_i y_i \varphi(x_i)$ and offset *b* obtained from a margin support vector x_j with $\alpha_j \in (0, C)$.

• No need to compute w either! Just need

$$w^{\top}\varphi(x) = \sum_{i=1}^{n} \alpha_i y_i \varphi(x_i)^{\top} \varphi(x) = \sum_{i=1}^{n} \alpha_i y_i k(x_i, x).$$

Get offset from

$$b = y_j - w^{\top} \varphi(x_j) = y_j - \sum_{i=1}^n \alpha_i y_i k(x_i, x_j)$$

for any margin support-vector x_j ($\alpha_j \in (0, C)$).

• Fitted a separating hyperplane in a high-dimensional feature space without ever mapping explicitly to that space.
