Eigenvalue Decomposition (EVD)

Eigenvalue decomposition plays a significant role in PCA. PCs are eigenvectors of $S = \frac{1}{n-1} \mathbf{X}^{\top} \mathbf{X}$ and PCA properties are derived from those of eigenvectors and eigenvalues.

- For any $p \times p$ symmetric matrix S, there exists p eigenvectors v_1, \ldots, v_p that are pairwise orthogonal and p associated eigenvalues $\lambda_1, \ldots, \lambda_p$ which satisfy the eigenvalue equation $Sv_i = \lambda_i v_i \ \forall i$.
- *S* can be written as $S = V\Lambda V^{\top}$ where
 - $V = [v_1, \dots, v_p]$ is a $p \times p$ orthogonal matrix $(VV^\top = V^\top V = I_p)$.
 - $\Lambda = diag\{\lambda_1, \ldots, \lambda_p\}$
 - If S is a **real-valued** matrix, then the eigenvalues are real-valued as well,

$$\lambda_i \in \mathbb{R}, \ \forall i.$$

• If S is **positive-semidefinite** matrix, then the eigenvalues are non-negative,

$$\lambda_i \geq 0, \ \forall i.$$

- To compute the PCA of a dataset X, we can:
 - **1** Estimate the covariance matrix using the sample covariance *S*.
 - 2 Compute the EVD of S using the R command eigen.

Singular Value Decomposition (SVD)

Unlike EVD, SVD **always** exists, even for non-square matrices.

- Real-valued $n \times p$ matrix **X** can be written as $X = UDV^{\top}$ where
 - U is an $n \times n$ orthogonal matrix: $UU^{\top} = U^{\top}U = I_n$
 - D is a $n \times p$ matrix with decreasing **non-negative** elements on the diagonal (the singular values) and zero off-diagonal elements.
 - V is a $p \times p$ orthogonal matrix: $VV^{\top} = V^{\top}V = I_p$
- SVD can be computed using very fast and numerically stable algorithms.
 The relevant R command is svd.

SVD and PCA

- Let $\mathbf{X} = UDV^{\top}$ be the SVD of the $n \times p$ data matrix \mathbf{X} .
- Note that

$$(n-1)S = \mathbf{X}^{\top}\mathbf{X} = (UDV^{\top})^{\top}(UDV^{\top}) = VD^{\top}U^{\top}UDV^{\top} = VD^{\top}DV^{\top},$$

using orthogonality $(U^{\top}U = I_n)$ of U.

- The eigenvalues of S are thus the diagonal entries of $\frac{1}{n-1}D^2$ and the columns of V are the eigenvectors of S.
- We also have

$$\mathbf{X}\mathbf{X}^{\top} = (UDV^{\top})(UDV^{\top})^{\top} = UDV^{\top}VD^{\top}U^{\top} = UDD^{\top}U^{\top},$$

using orthogonality $(V^{\top}V = I_p)$ of V.

SVD gives the optimal low-rank approximations of X:

$$\min_{\tilde{\mathbf{X}}} \|\tilde{\mathbf{X}} - \mathbf{X}\|^2$$
 s.t. $\tilde{\mathbf{X}}$ has maximum rank $r < n, p$.

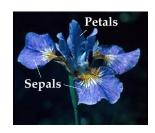

Keep only the r largest singular values of X, zeroing out the smaller singular values in the SVD.

Iris Data

50 samples from each of the 3 species of iris: setosa, versicolor, and virginica

Each measuring the length and widths of both sepal and petals

Collected by E. Anderson (1935) and analysed by R.A. Fisher (1936)

Iris Data

```
> iris1 <- iris[,-5]</pre>
```

> pairs(iris1)

Biplots

- PCA plots show the data items (rows of X) in the space spanned by PCs.
- Biplots allow us to visualize the original variables (columns of X) in the same plot.
- As for PCA, we would like the geometry of the plot to preserve as much of the covariance structure as possible.

Biplots

Recall that $X = [X^{(1)}, \dots, X^{(p)}]^{\top}$ and $\mathbf{X} = UDV^{\top}$ is the SVD of the data matrix.

• The 'full' PC projection of x_i is the *i*-th row of *UD*:

$$z_i = V^{\top} x_i = D^{\top} U_i^{\top}$$
, equivalently: $\mathbf{X}V = UD$.

• The *j*-th unit vector $\mathbf{e}_j \in \mathbb{R}^p$ points in the direction of the original variable $X^{(j)}$. Its PC projection η_j is:

$$\eta_j = V^{\top} \mathbf{e}_j = V_j^{\top}$$

(the j-th row of V)

- The projection of e_j indicates the weighting each PC gives to the original variables.
- Dot products between the projections gives entries of the data matrix:

$$x_{ij} = \sum_{k=1}^{p} U_{ik} D_{kk} V_{jk} = \langle D^{\top} U_i^{\top}, V_j^{\top} \rangle = \langle z_i, \eta_j \rangle.$$

- These relationships can be plotted in 2D by focussing on first two PCs.
- Quality depends on the proportion of variance explained by the first two PCs.

```

Biplots

There are other projections we can consider for biplots:

$$x_{ij} = \sum_{k=1}^{p} U_{ik} D_{kk} V_{jk} = \langle D^{\top} U_i^{\top}, V_j^{\top} \rangle = \langle D_{1:p,1:p}^{1-\alpha} U_{i,1:p}^{\top}, D_{1:p,1:p}^{\alpha} V_j^{\top} \rangle.$$

where $0 \le \alpha \le 1$, i.e., we change representation to

$$\tilde{z}_i = D_{1:p,1:p}^{1-\alpha} U_{i,1:p}^{\top}, \ \tilde{\eta}_j = D_{1:p,1:p}^{\alpha} V_j^{\top}$$

- case $\alpha = 1$:
 - Sample covariance of the projected points is:

$$\widehat{\mathsf{Cov}}\left(\widetilde{Z}\right) = \frac{1}{n-1} U_{1:n,1:p}^{\top} U_{1:n,1:p} = \frac{1}{n-1} I_p.$$

Projected points are uncorrelated and dimensions are equi-variance.

• Sample covariance between $X^{(i)}$ and $X^{(j)}$ is:

$$\hat{\mathbb{E}}(X^{(i)}X^{(j)}) = \frac{1}{n-1} \left(V D^{\top} D V^{\top} \right)_{i,j} = \frac{1}{n-1} \langle D_{1:p,1:p} V_i^{\top}, D_{1:p,1:p} V_j^{\top} \rangle$$

The angle between the projected variables corresponds to the correlation.

Multidimensional Scaling

Suppose there are n points \mathbf{X} in \mathbb{R}^p , but we are only given the $n \times n$ matrix \mathbf{D} of inter-point distances.

Can we reconstruct X?

Multidimensional Scaling

Rigid transformations (translations, rotations and reflections) do not change inter-point distances so cannot recover \mathbf{X} exactly. However \mathbf{X} can be recovered up to these transformations!

• Let $d_{ij} = ||x_i - x_j||_2$ be the distance between points x_i and x_j .

$$d_{ij}^{2} = \|x_{i} - x_{j}\|_{2}^{2}$$

$$= (x_{i} - x_{j})^{\top} (x_{i} - x_{j})$$

$$= x_{i}^{\top} x_{i} + x_{j}^{\top} x_{j} - 2x_{i}^{\top} x_{j}$$

- Let $\mathbf{B} = \mathbf{X}\mathbf{X}^{\top}$ be the $n \times n$ matrix of dot-products, $b_{ij} = x_i^{\top}x_j$. The above shows that \mathbf{D} can be computed from \mathbf{B} .
- Some algebraic exercise shows that **B** can be recovered from **D** if we assume $\sum_{i=1}^{n} x_i = 0$.

Multidimensional Scaling

- If we knew \mathbf{X} , then SVD gives $\mathbf{X} = UDV^{\top}$. As \mathbf{X} has rank $k = \min(n, p)$, we have at most k singular values in D and we can assume $U \in \mathbb{R}^{n \times k}$, $D \in \mathbb{R}^{k \times p}$ and $V \in \mathbb{R}^{p \times p}$.
- The eigendecomposition of B is then:

$$\mathbf{B} = \mathbf{X}\mathbf{X}^{\top} = UDD^{\top}U^{\top} = U\Lambda U^{\top}.$$

- This eigendecomposition can be obtained from B without knowledge of X!
- Let $\tilde{x}_i^{\top} = U_i \Lambda^{\frac{1}{2}}$ be the *i*th row of $U \Lambda^{\frac{1}{2}}$. Pad \tilde{x}_i with 0s so that it has length p.

$$\tilde{x}_i^{\top} \tilde{x}_j = U_i \Lambda U_j^{\top} = b_{ij} = x_i^{\top} x_j$$

and we have found a set of vectors with dot-products given by B.

• The vectors \tilde{x}_i differs from x_i only via the orthogonal matrix V so are equivalent up to rotation and reflections.

US City Flight Distances

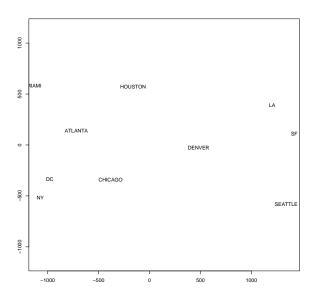

We present a table of flying mileages between 10 American cities, distances calculated from our 2-dimensional world. Using D as the starting point, metric MDS finds a configuration with the same distance matrix.

US City Flight Distances

```
library(MASS)
us <- read.csv("http://www.stats.ox.ac.uk/~sejdinov/teaching/data/uscities.csv")
## use classical MDS to find lower dimensional views of the data
## recover X in 2 dimensions
us.classical <- cmdscale(d=us,k=2)
plot(us.classical)
text(us.classical,labels=names(us))</pre>
```

US City Flight Distances

Lower-dimensional Reconstructions

In classical MDS derivation, we used all eigenvalues in the eigendecomposition of ${\bf B}$ to reconstruct

$$\tilde{x}_i = U_i \Lambda^{\frac{1}{2}}.$$

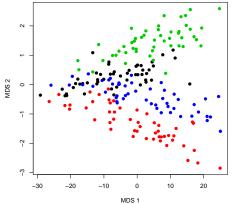

We can use only the largest $k < \min(n, p)$ eigenvalues and eigenvectors in the reconstruction, giving the 'best' k-dimensional view of the data.

This is analogous to PCA, where only the largest eigenvalues of $\mathbf{X}^{\mathsf{T}}\mathbf{X}$ are used, and the smallest ones effectively suppressed.

Indeed, PCA and classical MDS are duals and yield effectively the same result.

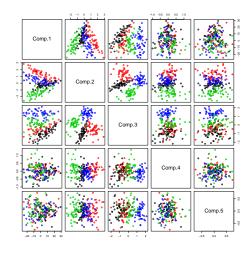

Crabs Data

```
library(MASS)
crabs$spsex=paste(crabs$sp,crabs$sex,sep="")
varnames<-c('FL','RW','CL','CW','BD')
Crabs <- crabs[,varnames]
Crabs.class <- factor(crabs$spsex)
crabsmds <- cmdscale(d= dist(Crabs),k=2)
plot(crabsmds, pch=20, cex=2,col=unclass(Crabs.class))</pre>
```

Crabs Data

Compare with previous PCA analysis. Classical MDS solution corresponds to the first 2 PCs.

Varieties of MDS

Generally, MDS is a class of dimensionality reduction techniques which represents data points $x_1, \ldots, x_n \in \mathbb{R}^p$ in a lower-dimensional space $z_1, \ldots, z_n \in \mathbb{R}^k$ which tries to preserve inter-point (dis)similarities.

- It requires only the matrix **D** of pairwise dissimilarities $d_{ij} = d(x_i, x_j)$. For example, we can use Euclidean distance $d_{ij} = ||x_i x_j||_2$, but other dissimilarities are possible.
- MDS finds representations $z_1, \ldots, z_n \in \mathbb{R}^k$ such that

$$||z_i-z_j||_2\approx d(x_i,x_j)=d_{ij},$$

and differences in dissimilarities are measured by the appropriate loss $\Delta(d_{ij}, ||z_i - z_j||_2)$.

Goal: Find Z which minimizes the stress function

$$S(\mathbf{Z}) = \sum_{i \neq j} \Delta(d_{ij}, ||z_i - z_j||_2).$$

Varieties of MDS

- Choices of (dis)similarities and stress functions lead to different objective (stress) functions and different algorithms.
 - Classical: preserves similarities (cmdscale)

$$S(\mathbf{Z}) = \sum_{i \neq j} (b_{ij} - \langle z_i - \overline{z}, z_j - \overline{z} \rangle)^2$$

Metric Shephard-Kruskal: distances, rather than squared distances

$$S(\mathbf{Z}) = \sum_{i \neq j} (d_{ij} - ||z_i - z_j||_2)^2$$

Sammon: preserves shorter distances more (sammon)

$$S(\mathbf{Z}) = \sum_{i \neq j} \frac{(d_{ij} - ||z_i - z_j||_2)^2}{d_{ij}}$$

 Non-Metric Shephard-Kruskal: ignores actual distance values, only preserves ranks (isoMDS)

$$S(\mathbf{Z}) = \min_{g \text{ increasing}} \frac{\sum_{i \neq j} (g(d_{ij}) - \|z_i - z_j\|_2)^2}{\sum_{i \neq j} \|z_i - z_j\|_2}$$

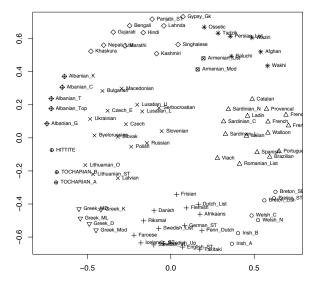

Example: Language data

Presence or absence of 2867 homologous traits in 87 Indo-European languages.

Example: Language data

Using MDS with non-metric (Sammon) scaling.

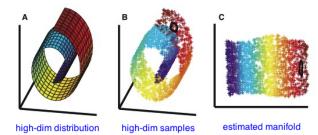

Nonlinear Dimensionality Reduction

Two aims of different varieties of MDS:

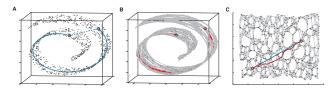

- To visualize the (dis)similarities among items in a dataset, where these (dis)disimilarities may not have Euclidean geometric interpretations.
- To perform nonlinear dimensionality reduction.

Many high-dimensional datasets exhibit low-dimensional structure ("live on a low-dimensional menifold").

Isomap

Isomap is a non-linear dimensional reduction technique based on classical MDS. Differs from other MDSs as it uses estimates of **geodesic distances** between the data points.

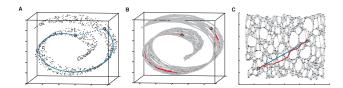

Tenenbaum et al. (2000)

Isomap

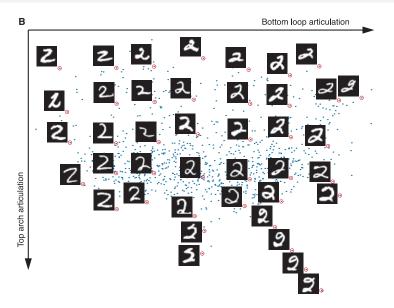

Isomap

- Calculate Euclidean distances d_{ij} for i, j = 1, ..., n between all data points.
- Form a graph G with n samples as nodes, and edges between the respective K nearest neighbours (K-Isomap) or between i and j if $d_{ij} < \epsilon$ (ϵ -Isomap).
- For i,j linked by an edge, set $d_{ij}^G = d_{ij}$. Otherwise, set d_{ij}^G to the shortest-path distance between i and j in G.
- Run classical MDS using distances d_{ii}^G .

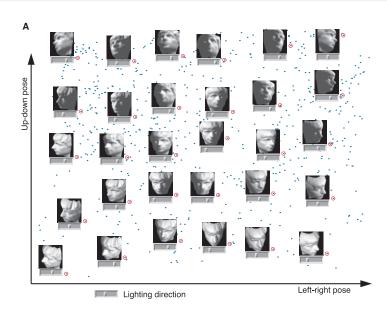

R function: isomap{vegan}.
