Supervised Learning

Naïve Bayes

Naïve Bayes

- Naïve Bayes: another plug-in classifier with a simple generative model it assumes all measured variables/features are independent given the label.
- Often used in text document classification, e.g. of scientific articles or emails.
- A basic standard model for text classification consists of considering a pre-specified dictionary of p words and summarizing each document i by a binary vector x_i where

$$x_i^{(j)} = \begin{cases} 1 & \text{if word } j \text{ is present in document} \\ 0 & \text{otherwise.} \end{cases}$$

- Presence of the word *i* is the *i*-the feature/dimension.
- To implement a plug-in classifier, we need a model for the conditional probability mass function $g_k(x) = \mathbb{P}(X = x | Y = k)$ for each class k = 1, ..., K.

Supervised Learning

laïve Bayes

Naïve Bayes

 Naïve Bayes is a plug-in classifier which ignores feature correlations¹ and assumes:

$$g_k(x_i) = \mathbb{P}(X = x_i | Y = k) = \prod_{j=1}^p \mathbb{P}(X^{(j)} = x_i^{(j)} | Y = k)$$
$$= \prod_{j=1}^p (\phi_{kj})^{x_i^{(j)}} (1 - \phi_{kj})^{1 - x_i^{(j)}},$$

where we denoted parametrized conditional PMF with $\phi_{kj}=\mathbb{P}(X^{(j)}=1|Y=k)$ (probability that j-th word appears in class k document).

• Given dataset, the MLE of the parameters is:

$$\hat{\pi}_k = \frac{n_k}{n}, \qquad \qquad \hat{\phi}_{kj} = \frac{\sum_{i:y_i = k} x_i^{(j)}}{n_k}.$$

Naïve Bayes

MLE:

$$\hat{\pi}_k = \frac{n_k}{n}, \qquad \qquad \hat{\phi}_{kj} = \frac{\sum_{i:y_i=k} x_i^{(j)}}{n_k}.$$

• A problem with MLE: if the ℓ -th word did not appear in documents labelled as class k then $\hat{\phi}_{k\ell}=0$ and

$$\mathbb{P}(Y = k | X = x \text{ with } \ell\text{-th entry equal to 1})$$

$$\propto \hat{\pi}_k \prod_{j=1}^p \left(\hat{\phi}_{kj}\right)^{x^{(j)}} \left(1 - \hat{\phi}_{kj}\right)^{1 - x^{(j)}} = 0$$

i.e. we will never attribute a new document containing word ℓ to class k (regardless of other words in it).

• This is an example of **overfitting**.

¹given the class, it assumes each word appears in a document independently of all others

Generative Learning

- Classifiers we have seen so far are generative: we work with a joint distribution $p_{X,Y}(x,y)$ over data vectors and labels.
- A learning algorithm: construct $f: \mathcal{X} \to \mathcal{Y}$ which predicts the label of X.
- Given a loss function L, the risk R of f(X) is

$$R(f) = \mathbb{E}_{p_{X,Y}}[L(Y,f(X))]$$

For 0/1 loss in classification, Bayes classifier

$$f_{\mathsf{Bayes}}(x) = \operatorname*{argmax}_{k=1,\dots,K} p(Y=k|x) = \operatorname*{argmax}_{k=1,\dots,K} p_{X,Y}(x,k)$$

has the minimum risk (Bayes risk), but is unknown since $p_{X,Y}$ is unknown.

- Assume a parameteric model for the joint: $p_{X,Y}(x,y) = p_{X,Y}(x,y|\theta)$
- Fit $\hat{\theta} = \operatorname{argmax}_{\theta} \sum_{i=1}^{n} \log p(x_i, y_i | \theta)$ and plug in back to Bayes classifier:

$$\hat{f}(x) = \operatorname*{argmax}_{k=1,\dots,K} p(Y=k|x,\theta) = \operatorname*{argmax}_{k=1,\dots,K} p_{X,Y}(x,k|\hat{\theta}).$$

Supervised Learning Logistic Regression

Generative vs Discriminative Learning

• Generative learning: find parameters which explain all the data available.

$$\hat{\theta} = \underset{\theta}{\operatorname{argmax}} \sum_{i=1}^{n} \log p(x_i, y_i | \theta)$$

Examples: LDA, QDA, naïve Bayes.

- Makes use of all the data available.
- Flexible modelling framework, so can incorporate missing features or unlabeled examples.
- Stronger modelling assumptions, which may not be realistic (Gaussianity, independence of features).
- **Discriminative learning**: find parameters that aid in **prediction**.

$$\hat{\theta} = \underset{\theta}{\operatorname{argmin}} \frac{1}{n} \sum_{i=1}^{n} L(y_i, f_{\theta}(x_i)) \quad \text{or} \quad \hat{\theta} = \underset{\theta}{\operatorname{argmax}} \sum_{i=1}^{n} \log p(y_i|x_i, \theta)$$

Examples: logistic regression, neural nets, support vector machines.

- Typically performs better on a given task.
- Weaker modelling assumptions: essentially no model on X, only on Y|X.
- Can overfit more easily.

Supervised Learning Logistic Regression

Logistic regression

• A discriminative classifier. Consider binary classification with $\mathcal{Y} = \{-1, +1\}$. Logistic regression uses a parametric model on the conditional Y|X, not the joint distribution of (X, Y):

$$p(Y = y | X = x; a, b) = \frac{1}{1 + \exp(-y(a + b^{\top}x))}.$$

• a, b fitted by minimizing the empirical risk with respect to log loss.

Hard vs Soft classification rules

• Consider using LDA for binary classification with $\mathcal{Y} = \{-1, +1\}$. Predictions are based on linear decision boundary:

$$\begin{split} \hat{y}_{\mathrm{LDA}}(x) &= & \operatorname{sign}\left\{\log\hat{\pi}_{+1}g_{+1}(x|\hat{\mu}_{+1},\hat{\Sigma}) - \log\hat{\pi}_{-1}g_{-1}(x|\hat{\mu}_{-1},\hat{\Sigma})\right\} \\ &= & \operatorname{sign}\left\{a + b^{\top}x\right\} \end{split}$$

for a and b depending on fitted parameters $\hat{\theta} = (\hat{\pi}_{-1}, \hat{\pi}_{+1}, \hat{\mu}_{-1}, \hat{\mu}_{+1}, \Sigma)$.

• Quantity $a + b^{T}x$ can be viewed as a soft classification rule. Indeed, it is modelling the difference between the log-discriminant functions, or equivalently, the log-odds ratio:

$$a + b^{\top} x = \log \frac{p(Y = +1 | X = x; \hat{\theta})}{p(Y = -1 | X = x; \hat{\theta})}.$$

- $f(x) = a + b^{T}x$ corresponds to the "confidence of predictions" and loss can be measured as a function of this confidence:
 - exponential loss: $L(y, f(x)) = e^{-yf(x)}$,
 - log-loss: $L(y, f(x)) = \log(1 + e^{-yf(x)}),$
 - hinge loss: $L(y, f(x)) = \max\{1 yf(x), 0\}.$

Linearity of log-odds and logistic function

 We can treat a and b as parameters in their own right in the model of the conditional Y|X.

$$\log \frac{p(Y = +1|X = x; a, b)}{p(Y = -1|X = x; a, b)} = a + b^{\top} x.$$

Solve explicitly for conditional class probabilities:

$$p(Y = +1|X = x; a, b) = \frac{1}{1 + \exp(-(a + b^{\top}x))} =: s(a + b^{\top}x)$$
$$p(Y = -1|X = x; a, b) = \frac{1}{1 + \exp(+(a + b^{\top}x))} = s(-a - b^{\top}x)$$

where $s(z) = 1/(1 + \exp(-z))$ is the **logistic function**.

Logistic Function

 $\nabla_z \log s(z) = s(-z)$

s(-z) = 1 - s(z)

 $\nabla_z s(z) = s(z)s(-z)$

 $\nabla_z^2 \log s(z) = -s(z)s(-z)$

Logistic Regression

- Not possible to find optimal a, b analytically.
- For simplicity, absorb a as an entry in b by appending '1' into x vector.
- Objective function:

$$\hat{R}_{\log} = \frac{1}{n} \sum_{i=1}^{n} -\log s(y_i x_i^{\top} b)$$

Differentiate wrt b:

$$\nabla_b \hat{R}_{\log} = \frac{1}{n} \sum_{i=1}^n -s(-y_i x_i^\top b) y_i x_i$$

$$\nabla_b^2 \hat{R}_{\log} = \frac{1}{n} \sum_{i=1}^n s(y_i x_i^\top b) s(-y_i x_i^\top b) x_i x_i^\top \succeq 0.$$

Fitting the parameters of the hyperplane

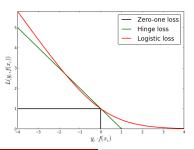

• Consider maximizing the conditional log likelihood:

$$\ell(a,b) = \sum_{i=1}^{n} \log p(Y = y_i | X = x_i) = \sum_{i=1}^{n} \log s(y_i(a + b^{\top} x_i)).$$

• Equivalent to minimizing the empirical risk associated with the log loss:

$$\hat{R}_{\log}(f_{a,b}) = \frac{1}{n} \sum_{i=1}^{n} -\log s(y_i(a+b^{\top}x_i)) = \frac{1}{n} \sum_{i=1}^{n} \log(1 + \exp(-y_i(a+b^{\top}x_i)))$$

over all linear soft classification rules $f_{a,b}(x) = a + b^{\top}x$.

Logistic Regression

Logistic Regression

- Second derivative is positive-definite: objective function is **convex** and there is a single unique global minimum.
- Many different algorithms can find optimal b, e.g.:
 - Gradient descent:

$$b^{\text{new}} = b + \epsilon \frac{1}{n} \sum_{i=1}^{n} s(-y_i x_i^{\top} b) y_i x_i$$

Stochastic gradient descent:

$$b^{\mathsf{new}} = b + \epsilon_t \frac{1}{|I(t)|} \sum_{i \in I(t)} s(-y_i x_i^\top b) y_i x_i$$

where I(t) is a subset of the data at iteration t, and $\epsilon_t \to 0$ slowly $(\sum_t \epsilon_t = \infty, \sum_t \epsilon_t^2 < \infty).$

Newton-Raphson:

$$b^{\mathsf{new}} = b - (\nabla_b^2 \hat{R}_{\mathsf{log}})^{-1} \nabla_b \hat{R}_{\mathsf{log}}$$

This is also called **iterative reweighted least squares**.

Conjugate gradient, LBFGS and other methods from numerical analysis.

Logistic Regression vs. LDA

Linearly separable data

Both have linear decision boundaries and model log-posterior odds as

$$\log \frac{p(Y = +1|X = x)}{p(Y = -1|X = x)} = a + b^{\top} x$$

 LDA models the marginal density of x as a Gaussian mixture with shared covariance

$$g(x) = \pi_{-1}\mathcal{N}(x; \mu_{-1}, \Sigma) + \pi_{+1}\mathcal{N}(x; \mu_{+1}, \Sigma)$$

and fits the parameters $\theta = (\mu_{-1}, \mu_{+1}, \pi_{-1}, \pi_{+1}, \Sigma)$ by maximizing joint likelihood $\sum_{i=1}^{n} p(x_i, y_i | \theta)$. a and b are then determined from θ .

• Logistic regression leaves the marginal density g(x) as an **arbitrary density function**, and fits the parameters a,b by maximizing the conditional likelihood $\sum_{i=1}^{n} p(y_i|x_i;a,b)$.

Assume that the data is linearly separable, i.e. there is a scalar α and a vector β such that $y_i(\alpha + \beta^{\top} x_i) > 0$, i = 1, ..., n. Let c > 0. The empirical risk for $a = c\alpha$, $b = c\beta$ is

$$\hat{R}_{log}(f_{a,b}) = \frac{1}{n} \sum_{i=1}^{n} \log(1 + \exp(-cy_i(\alpha + \beta^{\top}x_i)))$$

which can be made arbitrarily close to zero as $c \to \infty$, i.e. soft classification rule becomes $\pm \infty$ (overconfidence).

Supervised Learning

Multi-class logistic regression

Logistic Regression: Summary

The **multi-class/multinomial** logistic regression uses the **softmax** function to model the conditional class probabilities $p(Y = k | X = x; \theta)$, for K classes k = 1, ..., K, i.e.,

$$p\left(Y = k | X = x; \theta\right) = \frac{\exp\left(w_k^\top x + b_k\right)}{\sum_{\ell=1}^K \exp\left(w_\ell^\top x + b_\ell\right)}.$$

Parameters are $\theta = (b, W)$ where $W = (w_{ki})$ is a $K \times p$ matrix of weights and $b \in \mathbb{R}^K$ is a vector of bias terms.

- Makes less modelling assumptions than generative classifiers: often resulting in better prediction accuracy.
- Diverging optimal parameters for linearly separable data: need to regularise / pull them towards zero.
- A simple example of a generalised linear model (GLM), for which there is a well established statistical theory:
 - Assessment of fit via deviance and plots,
 - Well founded approaches to removing insignificant features (drop-in deviance test, Wald test).

Regularization

- Flexible models for high-dimensional problems require many parameters.
- With many parameters, learners can easily overfit.
- Regularization: Limit flexibility of model to prevent overfitting.
- Add term penalizing large values of parameters θ .

$$\min_{\theta} \hat{R}(f_{\theta}) + \lambda \|\theta\|_{\rho}^{\rho} = \min_{\theta} \frac{1}{n} \sum_{i=1}^{n} L(y_{i}, f_{\theta}(x_{i})) + \lambda \|\theta\|_{\rho}^{\rho}$$

where $\rho \ge 1$, and $\|\theta\|_{\rho} = (\sum_{j=1}^{p} |\theta_{j}|^{\rho})^{1/\rho}$ is the L_{ρ} norm of θ (also of interest when $\rho \in [0,1)$, but is no longer a norm).

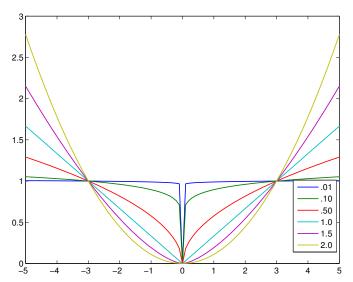

- Also known as **shrinkage** methods—parameters are shrunk towards 0.
- λ is a **tuning parameter** (or **hyperparameter**) and controls the amount of regularization, and resulting complexity of the model.

Types of Regularization

- Ridge regression / Tikhonov regularization: $\rho = 2$ (Euclidean norm)
- LASSO: $\rho = 1$ (Manhattan norm)
- Sparsity-inducing regularization: $\rho < 1$ (nonconvex for $\rho < 1$)
- Elastic net regularization: mixed L_1/L_2 penalty:

$$\min_{\theta} \frac{1}{n} \sum_{i=1}^{n} L(y_i, f_{\theta}(x_i)) + \lambda \left[(1-\alpha) \|\theta\|_2^2 + \alpha \|\theta\|_1 \right]$$

Regularization

 L_{ρ} regularization profile for different values of ρ .

Supervised Learning

L₁ promotes sparsity

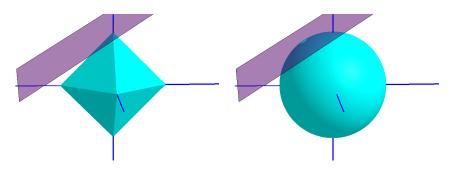

Figure: The intersection between the L_1 (left) and the L_2 (right) ball with a hyperplane.

 L_1 regularization often leads to optimal solutions with many zeros, i.e., the regression function depends only on the (small) number of features with non-zero parameters.
